Abstract
Dysregulation of sodium and potassium has a characteristic role in the development of various cardiovascular disease. In the present study, it sought to explore the sodium and potassium influenced by thyroid hormone disorders in sera of patients with cardiovascular disease. The study population consisted of 51 female patients with cardiovascular disease in combination with thyroid dysfunction. Thyroid function disorders were found to have hypothyroidism in 47% of patients and hyperthyroidism in 53% of patients. A significant increase in sodium and potassium concentrations were found in both patient groups. A positive significant correlation was observed between Na concentration and TSH level in sera of patients with hypothyroidism. A significant increase in sodium and potassium concentrations were found in both patient groups. A positive significant correlation was observed between Na concentration and T4 level in sera of patients with hyperthyroidism in 53% of patients. A significant increase in sodium and potassium concentrations were found in both patient groups. A positive significant correlation was observed between Na concentration and TSH level in sera of patients with hypothyroidism.

Keyword: cardiovascular, thyroid, sodium, potassium.

Introduction
Cardiovascular diseases refer to the class of diseases that involve the heart or blood vessels, such as coronary heart disease, angina, heart attack, and stroke. These diseases have similar causes, mechanisms, and treatment.

The heart is a major target organ for thyroid hormone action. Many symptoms and signs recognized in patients with overt hyperthyroidism and hypothyroidism are due to the increased or reduced action of thyroid hormone on the heart and the vascular system, respectively. Both hyperthyroidism and hypothyroidism produce changes in cardiac contractility, myocardial oxygen consumption, cardiac output, blood pressure, and systemic vascular resistance.

On the other hand, it is becoming increasingly apparent that acute and chronic cardiovascular disease may be altered by thyroid hormone metabolism and contribute to cardiovascular impairment. Most of the molecular and cellular mechanisms responsible for the cardiovascular effects of thyroid hormone have been clarified. Total thyroxin (T4) and total triiodothyronine (T3) are synthesized by the thyroid gland in response to TSH. The thyroid gland primarily secretes T4 (85%), which is converted to T3 by 5-mono-deiodination in the liver, kidney, and skeletal muscle. The heart relies mainly on serum T3 because no significant myocyte intracellular deiodinase activity takes place, and it appears that T3 and not T4, is transported into the myocyte. Thyroid hormones may exert both genomic and nongenomic effects on cardiac myocytes. The genomic effects of thyroid hormone are mediated by the transcriptional activation or repression of specific target genes that encode both structural and functional proteins. Those include sarcoplasmatic reticulum Ca-ATPase, and its inhibitor phospholamban, α-myosin heavy chain, β myosin heavy chain, and the ion channels sodium potassium ATPase (Na-K-ATPase), the voltage-gated, potassium channels, and the sodium calcium exchanger. Thyroid hormone also has nongenomic effects on the cardiac myocyte and on the systemic vasculature. These effects of T3 can occur rapidly and do not involve mediated transcriptional events.

These T3-mediated effects include changes in various membrane ion channels for sodium, potassium, and calcium, effects on actin polymerization, adenine nucleotide translocator1 in the mitochondrial membrane, and a variety of intracellular signaling pathways in the heart and vascular smooth muscle cells. Together the nongenomic and genomic effects of T3 act in concert to regulate cardiac function and cardiovascular hemodynamics.

The aims of the present study is to evaluate the influence of thyroid hormone on sodium...
and potassium levels in sera of female patients with cardiovascular disease.

**Subjects and Methods**

**Subjects:** The study samples consisted of 40 healthy individuals as a control group and 51 female patients with cardiovascular diseases of different types in combination with thyroid dysfunction attending Al Bittar Hospital in Baghdad city during (May – September) and diagnosis by Dr. Ali Abdul Amir.

**Serum Sampling:** Venous blood (5ml) were taken from healthy donors and patients. Blood samples were centrifuged at (3000 rpm) for 10min, after coagulation serum thus separated and stored at -20°C until being used.

**Methods:**
- **Determination of serum T<sub>3</sub> and T<sub>4</sub> levels:** Total triiodothyronine and total thyroxin in sera of control and patients were determined using Enzyme Linked Fluorescent Assay (ELFA)(Bio Merieux kit)by VIDAS instruments. The assay principle combines an enzyme immunoassay competition method with a final fluorescent detection (ELFA).
- **Determination of serum TSH level:** Serum TSH of control and patients was determination using Bio Merieux kit& ELFA technique on the VIDAS instruments. The assay principle combines a one-step enzyme immunoassay sandwich method with a final fluorescent detection (ELFA).
- **Determination of Na and K concentration:** Sodium and potassium concentration were determined in the sera of control and patients using flame photometry method.

**Statistical Analysis:** The findings were expressed as the mean ±SD with standard error. Statistical and correlation analyses were performed using the student t-test, and spearman correlation test respectively. The P value < 0.05 was accepted as statistically significant. Spss (for windows, version 10.0) was used for statistical analyses.

**Results**

Thyroid hormones T<sub>3</sub>, T<sub>4</sub> ,TSH were measured in the sera of the control and patients with cardiovascular disease. The results represented in Table (1) enable us to classify the studied patients with cardiovascular disease into two groups as far as thyroid dysfunction is concerned. Group I with hyperthyroidism, since they showed normal level of TSH with increase levels of T<sub>3</sub> and T<sub>4</sub> or decreased level of TSH with normal levels of T<sub>3</sub> and T<sub>4</sub>. Group II with hypothyroidism, since they showed normal level of TSH with decrease levels of T<sub>3</sub> and T<sub>4</sub> or increase level of TSH with normal levels of T<sub>3</sub> and T<sub>4</sub>.

The mean value presented in Fig.(1) revealed a highly significant increase in serum potassium (P<0.01) and sodium (P<0.01) concentrations respectively of both thyroid dysfunction patient groups with cardiovascular disease in comparison with that of the control group.

In order to check the alteration of sodium and potassium levels by thyroid hormones disorder, a correlation study between T<sub>3</sub>,T<sub>4</sub> and TSH with Na and K was carried out in the sera of patients with CVD group I who had hyperthyroidism and in the sera of those patients with CVD group II who had hyperthyroidism Table (1).

* correlation is significant at the 0.05 level (2-tailed).

A significant positive correlation was found between Na and T4 in the sera of patients with CVD (group I) who had hyperthyroidism while a significant negative correlation was found between Na and TSH in the sera of patients with CVD (group II) who had hyperthyroidism.

Discussion

The relationship between thyroid status and the cardiovascular system is not unidirectional (4). Thyroid hormone metabolism is altered in many patients with acute or chronic cardiac disease, as it is in patients with other nonthyroidal illnesses (6).

Treatment with amiodarone (is an iodine – rich antiarrhythmic drug with a structural resemblance to thyroid hormones T3 and T4) may lead to changes hypothyroidism or thyrotoxicosis (16).

In the present study 47% of the studied patients appear to have hypothyroidism, since they have increase level of TSH with normal levels of T3 and T4 or normal level of TSH with decrease levels of T3 and T4 (17). This was in agreement with the result obtained by Hamilton et. al. (1996) who reported that in a population of patients with advanced heart failure, a reduction in T3 with an increase in reverse T3 was identified in many patients, with abnormally low ratio of T3/reverseT3 being the strongest predictor of mortality (18). Also Tinoco RS, et. al.(2009) showed that thyroid function disorders in patients with chronic stable heart failure were observed in 27.1% of the subjects: sick euthyroid syndrome (12.5%), subclinical hypothyroidism 10.4% and overt hypothyroidism (6.2%) (19). Ascheim DD. and Hryniewicz K. (2002) reported that seven percent of patients with congestive heart failure were found to have primary hypothyroidism and 34% have a low T3 state (20). In patients with acute myocardial infarction, serum T3, T4 decreased while reverse T3 increased and TSH level remained within normal range (21,22,23,24). Simkoj et. al. (2002) reported that the complex effect of amiodarone on thyroid function ranges from mild abnormalities of thyroid function tests to...
overt thyrotoxicosis or hypothyroidism\textsuperscript{(25)}. While Trifanescu R. et al. (2004) reported that amiodorone–induced thyrotoxicosis developed in 31 cardiac patients (49.2%); 17 patients (27%) remained euthyroid patients from iodine deficient areas developed more frequent hyperthyroidism (9.\% vs.40.4\%) at significant lower cumulative doses of amiodarone and never hyperthyroidism. Overt hyperthyroidism prevails (29/31 patients) \textsuperscript{(26)}. Mean while this is agreement with the results that obtained throughout the present study where 27 patients with cardiovascular disease (53\%) appear to have hyperthyroidism (Table (1)).

A significant effect of thyroid hormones on the heart results from an interaction with specific nuclear receptors in cardiac myocytes. However, rapid thyroid hormone effects on ion transport functions have been elicited in isolated cardiac myocytes and may be independent of protein synthesis \textsuperscript{(3)}. In cardiac muscle, the transarcolemmal sodium gradient established by Na/K ATPase activity is essential not only for generating the rapid upstroke of the action potential but also for driving a number of ion-exchange and transport processes crucial for normal cellular function, ion homeostasis and the control of cell volume\textsuperscript{(27)}.

Various cardiovascular disease such as ischemic heart disease, myocardial infarction and ventricular dystrophy are the most common cardiovascular problems. As proved by various studies, dysregulation of sodium Na, potassium K, calcium Ca, has a characteristic role in the development of various cardiovascular diseases. Basic cellular abnormalities in various cardiovascular diseases is an inability to maintain a normal transmembrane gradient\textsuperscript{(28)}.

The plasma sodium and potassium concentrations were found to be altered in cardiovascular patients. This has been indicated by several previous investigators suggesting that increases in H\textsuperscript{+} exchanger activity might be involved in this functional impairment\textsuperscript{(29)}.

In the present study serum sodium and potassium measurements Fig.(1) showed a significant increase (p<0.01) in serum sodium and potassium concentrations of patients with cardiovascular disease in both groups: group I who had hyperthyroidism and group II who had hypothyroidism. This was in agreement with the result that obtained by En-zhi JIA. et. al. (2007) who indicated that females were at greater risk of hypernalremia and the serum sodium concentration was significantly increase and negatively associated with coronary atherosclerosis\textsuperscript{(30)}, on the other hand disagreed with the results obtained by Shahid SM.et.al. (2005) who reported that serum sodium level was significantly decreased and serum potassium level significantly increased in cardiac patients\textsuperscript{(31)}. Also the present result disagreed with the results obtained by Harrison TR. (1930) who indicated that plasma and muscle magnesium and potassium concentrations are reduced in heart failure\textsuperscript{(32)}.

A non significant correlation was found in the present study between K concentration and thyroid hormones level in the sera of patients with cardiovascular disease while a significant positive correlation was found throughout this study between Na concentration and T\textsubscript{4} in level in the sera of patients with cardiovascular disease group I who had hyperthyroidism and a significant negative correlation was found between Na concentration and TSH level in the sera of patients with cardiovascular disease group II who had hypothyroidism (Table (2)). This finding indicated that Na ion effected by thyroid hormone changes that occurs in sera of patients with cardiovascular disease while K ion did not effected by alteration in thyroid hormone level in the sera of the same patients under this study.
